

## Appendix D. Catchment Characteristics

The following soil characteristics are summarised from Landcare Research's web page <http://smap.landcareresearch.co.nz/glossary>.

### D.1 Potential Rooting Depth

Potential rooting depth describes the depth of soil that a plant can exploit water from. Such a layer may be defined by penetration resistance, poor aeration or very low available water capacity. In soil with a deep potential rooting depth, some grass roots will penetrate to over 100 cm deep. When plants extract water and nutrients from deep in the soil, they are more resistant to drought and hence require less irrigation water and the soil is less prone to leaching.

Potential rooting depth classes are described fully in Webb and Wilson (1995) and are as summarised in **Table D.1**.

**Table D-1. Potential rooting depth classes (m).**

Depth profile	Min	Max
Very shallow	0.15	0.24
Shallow	0.25	0.44
Slightly deep	0.45	0.59
Moderately deep	0.6	0.89
Deep	0.9	1.19
Very deep	1.2	1.5

### D.2 Plant Available Water (PAW)

Plant available water (PAW) is the amount of water potentially available to plant growth that can be stored in the soil to a depth of 100 cm, or to the potential rooting depth (whichever is the lesser). PAW takes into account variations in soil horizons and is expressed in units of millimetres of water, i.e. in the same way as rainfall. A PAW of 100 mm implies that 10% of the soil volume is water available to plants. **Table D-2** outlines PAW classes utilised for this study (extracted from the fundamental soils layer).

Plants can only extract water where roots can grow. Thus, where a root barrier occurs within 100 cm, the PAW reported will be the PAW to the root barrier. It is important to recognise that PAW is a potential value and not all the water is equally available. For example, as the soil dries out the water becomes more difficult to extract. As a general 'rule of thumb', plant growth will begin to slow down when 50% of PAW has been extracted. In the case of shallow rooting crops (e.g. potatoes) PAW is characterised as the available water to the maximum rooting depth.

**Table D-2.** Plant available water classes (mm).

Depth profile	Min	Max
Very low	0	29
Low	30	59
Moderate	60	89
Moderately high	90	149
High	150	249
Very high	250	350

### D.3 Depth to Slow Permeable Horizon

Depth to a slowly permeable horizon describes the minimum and maximum depths (in metres) to a horizon where the permeability is less than 4 mm/hr as measured by techniques outlined in Griffiths (1985). **Table D-3** summarises the depth for each class defined by techniques outlined in Griffiths (1985). If no slowly permeable horizon is observed, the taxon is allocated to Class 6.

**Table D-3.** Depth to slow permeable horizon (mm).

Class	Min	Max
1	0	0.44
2	0.45	0.59
3	0.60	0.89
4	0.90	1.19
5	1.20	1.49
6	Not encountered	

### D.4 Drainage Class

Soil drainage class is a classification that indicates how wet a soil is likely to be under high rainfall conditions. Well-drained soils allow water to drain through the profile in all periods of the year. Poorly drained soils either have a water table close to the surface, or a compact subsurface layer that limits the rate that water can drain through the soil. Imperfectly drained soils are in an intermediate condition between well-drained and poorly drained.

Drainage classes are assessed using criteria of soil depth and duration of water tables inferred from soil colours and mottles, or from reference to diagnostic horizons, as described in **Table D-4**. Drainage classes used here are the same as those used in the NZ Soil Classification (Hewitt, 1993) and outlined by Milne *et. al.* (1995).

**Table D-4. Soil drainage classes.**

Class	Description	Water table depth below A horizon	Compacted subsurface depth	Low chroma on ped or cut surfaces	High Chroma redox mottles
		(cm)	(cm)	(%)	(%)
1	Very poor	1	≤10	≥50	
2	Poor	≤15	≤30	≥50	
3	Imperfect	≤15	≤30	≤50	and/or ≥2
		>15	30–90	≥50	
4	Moderately well		30–90		≥2
			60–90	≥50	
5	Well		>90		<2

## D.5 Permeability

Permeability is the rate that water moves through saturated soil and hence defines the ability of a soil to drain (regardless of external influences on water tables, e.g. being low-lying in the landscape). The permeability of a soil profile is affected by texture, structure and soil density and is related to potential rooting depth, depth to a slowly permeable horizon and internal soil drainage. Permeability of a soil profile is often expressed as two values such as ‘moderate over slow’. This is where a layer of moderate-draining soil sits above a layer of slow-draining soil. Permeability of a profile under extended rainfall conditions is governed by the permeability of the layer that is most slowly permeable. Permeability classes and their equivalent flow rates (mm/h) from Clayden and Webb (1994) are as shown in **Table D-5**.

**Table D-5. Soil permeability classes.**

Class	Rate (mm/hr)
Slow	< 4
Moderate	4-72
High	> 72

## D.6 Calculated Statistics

An overview of the sub-catchment average statistics for area, slope, elevation, depth to groundwater, permeability, and geology for each SOURCE model sub-catchment are provided in **Table D-6** and

**Table D-7** for the Kaituna and Rangitāiki WMAs respectively.

The sub catchment area, mean slope, and mean elevation for the Kaituna and Rangitāiki WMAs were calculated from the LINZ 15 m Digital Elevation Model using QGIS.

Depth to groundwater was estimated based on the median sub-catchment elevation and estimated groundwater table depth. The depth of the groundwater table was estimated in GIS by sampling the river channel elevation from the DEM, and assuming the depth to groundwater table for each sub-catchment was equal to half the elevation range from the minimum to 80<sup>th</sup> percentile elevation of sampled points. The sub-catchment depth to

groundwater was then calculated as the median sub-catchment elevation minus the depth of the groundwater table.

**Table D-6. Calculated Statistics for the Kaituna**

SC ID	Area (km2)	Weighted Average		
		Elevation (m aMSL)	Slope (Degrees)	Depth to Groundwater (m)
SCID1	31.1	521.9	6.3	136.2
SCID2	12.6	497.3	9.9	103.1
SCID3	15.1	423.3	9.7	121.6

## D.7 Soil Classes

The weighted average soil properties of each sub-catchment were calculated from S-map data. Classes were assigned for drainage, potential rooting depth and plant available water which are described in **Section D.1**, **Section D.2** and **Section D.4**. A summary of the sub-catchment averaged values for the Kaituna and Rangitāiki WMAs are presented in **Table D-8** and **Table D-9** respectively.

**Table D-8. Weighted average soil classes for Kaituna**

SC ID	Weighted Average				
	Drainage Class	Potential Rooting Depth Class	Plant Available Water	Soil Permeability (mm/d)	Soil Depth (mm)
SCID1	5.0	2.1	2.5	4.4	1011.3

## D.8 Geological Classes

The weighted average vertical hydraulic conductivity and geological permeability for each sub catchment is outlined in the tables below, with the main rock type from the geological map and the percentage occurrence within each catchment.

**Table D-10. Rock hydraulic conductivity lookup table for Kaituna**

	Rock Hydraulic Conductivity Lookup Table											
	MUDSTONE	TEPHRA	ANDESITE	IGNIMBRITE	PEAT	BRECCIA	SANDSTONE	SAND	PUMICE	RHYOLITE	BROKEN FORMATION	GRAVEL
